

Webhook Events

Webhook Events

Allstar uses webhooks to notify your application when requests made by your account have an event.

All integrations should establish a webhook endpoint to listen for events:

Webhook requests

All webhook requests will have the following structure:

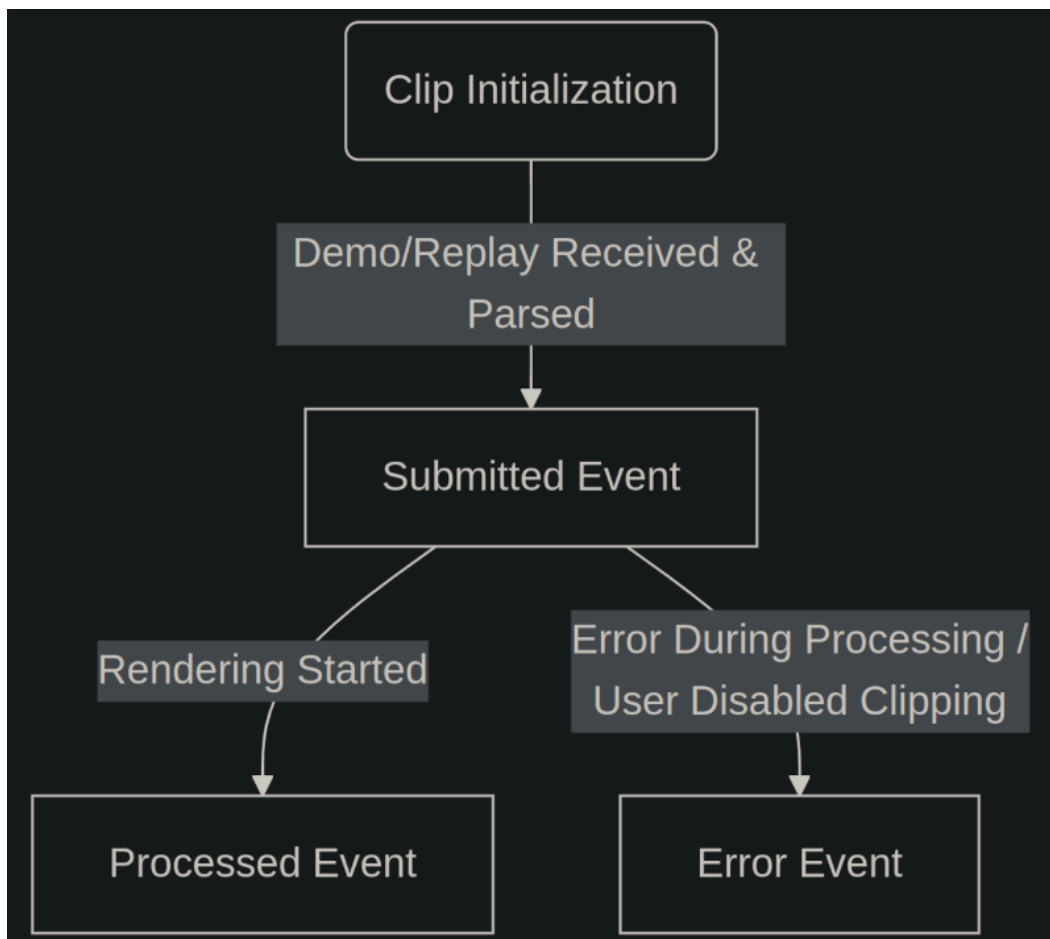

```
method: POST
url: webhookUrl
headers:
  Content-Type: application/json
  Authorization: authString
body: eventData
```

- ``webhookUrl`` - The full URL to your API endpoint.
 - You can configure the ``webhookUrl`` per each clip request you send to Allstar (See [clip request API reference](#).
 - The specified ``webhookUrl`` in the initial clip request will be used later to send related webhook events to.
 - If the ``webhookUrl`` was not specified for a clip request, your default webhook URL (assigned during onboarding) will be used.
- ``eventData`` - The body of the request which is the event data in JSON. Data structure is specific to event type.
- ``authString`` - The authorization string for our requests against your API. See [Authentication](#)

Retry policy: We will retry the event webhook request every 15 minutes until we receive a ``2xx`` response from your API or until we try 8 times.

Clip Lifecycle Events

Below are all the events that trigger webhook requests.

Clip Events

Clip Submitted

We've received your clip request and started processing it.

Clip Processed

The clip has been created and is ready to display to the user.

Clip OnDemand

The clip has been staged but not rendered; the iframe is ready to display to the user and the user can initiate clip rendering via the iframe.

Clip Error

Sometimes an error may occur during the clip creation process. This event will be surfaced and an error message in the body of the event provide additional context.

Some common/possible errors you may encounter:

- Pre-clipping errors:
 - User disabled clipping
 - Failed to compress parser output.
 - Failed to decompress demo file.
 - Failed to download demo file.
 - Failed to download demo ({reason})

- Failed to encode compressed parser output.
- Failed to enqueue message.
- Failed to get signed URL from Facelt.
- Failed to marshal message.
- Failed to marshal parser output.
- Failed to parse demo file.
- Failed to unmarshal data
- Failed to upload demo file.
- Clipping related errors:
 - CC0001(DataError))
 - CC0002(DownloadError)
 - CC0005(NoOutputError)
 - CC0007(PostProcessingError)
 - CC0008(PostProcessingTimeout)
 - CC0011(GameLaunchError)
 - CC0012(BadAssetError)
 - CC0014(StorageError)
 - CC0015(WindowPriorityError)
 - CC0016(BadOutputError)
 - CC0018(VideoError)
 - CC0019(VideoRequestError)
 - CC0020(StorageError)
 - CC3001(LeagueGameLaunchTimeout)
 - CC3002(LeagueClientAPIError)
 - CC3003(LeagueError)
 - CC3006(LeagueReplayTimeout)
 - CC4001(CS2Error)
 - CC4002(CS2Error)
 - CC4008(CS2Error)
 - CC4012(CS2Error)
 - CC5004(FortniteGameStateError)

User Disabled Clipping

A user may disable clipping on a per partner basis; when a user has disabled clipping on a per partner basis, an error message will be surfaced via the webhook with this message: ``User disabled clipping. | An error occurred processing the clip.``

Example Payloads

See [Event data examples](#) for JSON data examples for each event type.

Webhook Authorization

We will send an authorization string to you with the webhook requests, so you can authenticate requests from Allstar.

Our webhook requests sent to your API endpoint can be authenticated with a *header*.

```
Authorization: {string}
```

The value of Authorization ``string`` in the header is saved in your partner configuration and will be global for all webhook requests to you. If no authorization string is configured, we don't send webhook requests by default.

You can configure the webhook authorization on the [dashboard](#).

How you authenticate your webhook is up to you, here are some examples:

Token

```
Authorization: "token 123456"
```

Bearer

```
Authorization: "bearer 098766"
```

Raw

```
Authorization: "DJC32-557BHJS-JBS72-62JK"
```

Event data examples

Clip ``Submitted``:

```
{
